Beulie pond

**Amélie HUMBRECHT**  
1st year PhD student

Réponse spatiale de contaminants organiques et inorganiques d'origine anthropique  
à l'échelle de l'étang de la Beulie, Egoutier, France

PhD director: Lydie LE FORESTIER  
Co-Supervisor : Anaëlle SIMONNEAU

- One of the Water Framework Directive initial objectives -> reach waterbodies' good ecological state before 2015 -> due date postponed to 2027

~80% occur in the particulate phase, including suspended particulate matters -> considered themselves as contaminants

(Oelkers et al., 2011 and included references, modified by Ledieu, 2020)

- **Inorganic ones** -> trace metals mostly, also studied in the particulate phase (Demlie et al. 2006; Farag et al. 2007)
- **Organic ones** -> particulate phase not always targetted (Bound et al. 2006; Meyer et al. 2006)

- Mostly anthropogenic releases
- Wastewater Treatment Plants : not only trace metals, also organic molecules

- One of the Water Framework Directive initial objectives -> reach waterbodies' good ecological state before 2015 -> due date postponed to 2027

~80% occur in the particulate phase, including suspended particulate matters -> considered themselves as contaminants

**We should not only focus on the bulk matrix -> decompose sediments and identify what the reactive phases are transporting (Tablin 2018)**

(Oelkers et al., 2011 et références)

- **Inorganic ones** -> trace metals mostly, also studied in the particulate phase (Demlie et al. 2006; Farag et al. 2007)
- **Organic ones** -> particulate phase not always targetted (Bound et al. 2006; Meyer et al. 2006)

- Mostly anthropogenic releases
- Wastewater Treatment Plants : not only trace metals, also organic molecules

**What we already know:**

-> Organic and inorganic contaminants are released in hydrosystems at sometimes high levels of concentration, and are, for lot of them, also quantified in the particulate phase

**What we are looking for:**

- > Which compartments are the most likely to adsorb those substances ? What are the involved mechanisms ?
- > Are those processes reversible ?
- > What is the fate of these contaminants at catchment scales ?

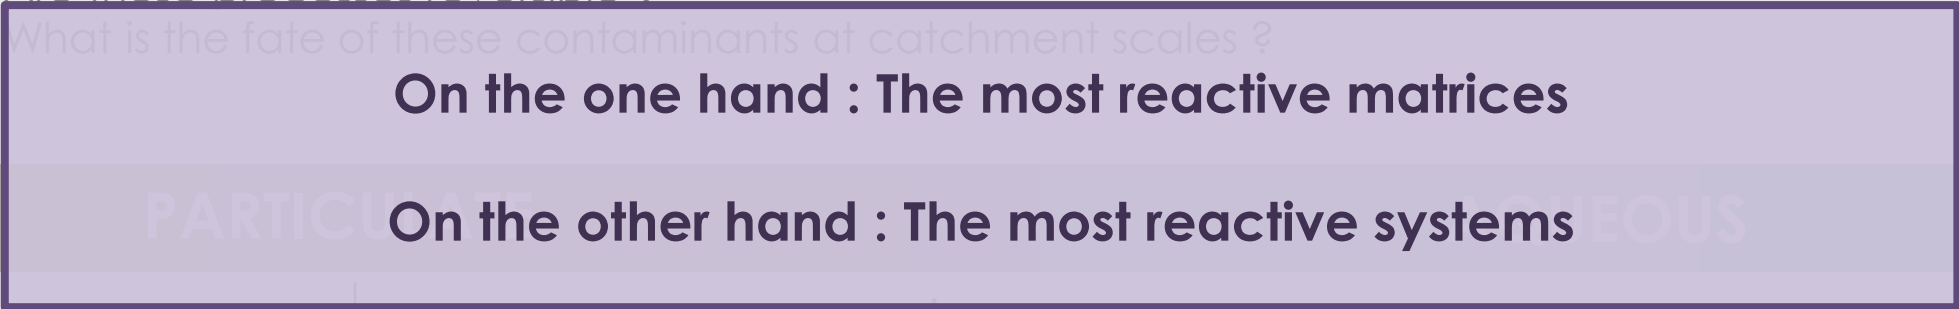

• **What we already know:**

-> Organic and inorganic contaminants are released in hydrosystems at sometimes high levels of concentration, and are, for lot of them, also quantified in the particulate phase

• **What we are looking for:**

- > Which compartments are the most likely to adsorb those substances ? What are the involved mechanisms ?
- > Are those processes reversible ?
- > What is the fate of these contaminants at catchment scales ?

**Sediment/Colloids/Water Continuum**

What would be the perfect candidate?

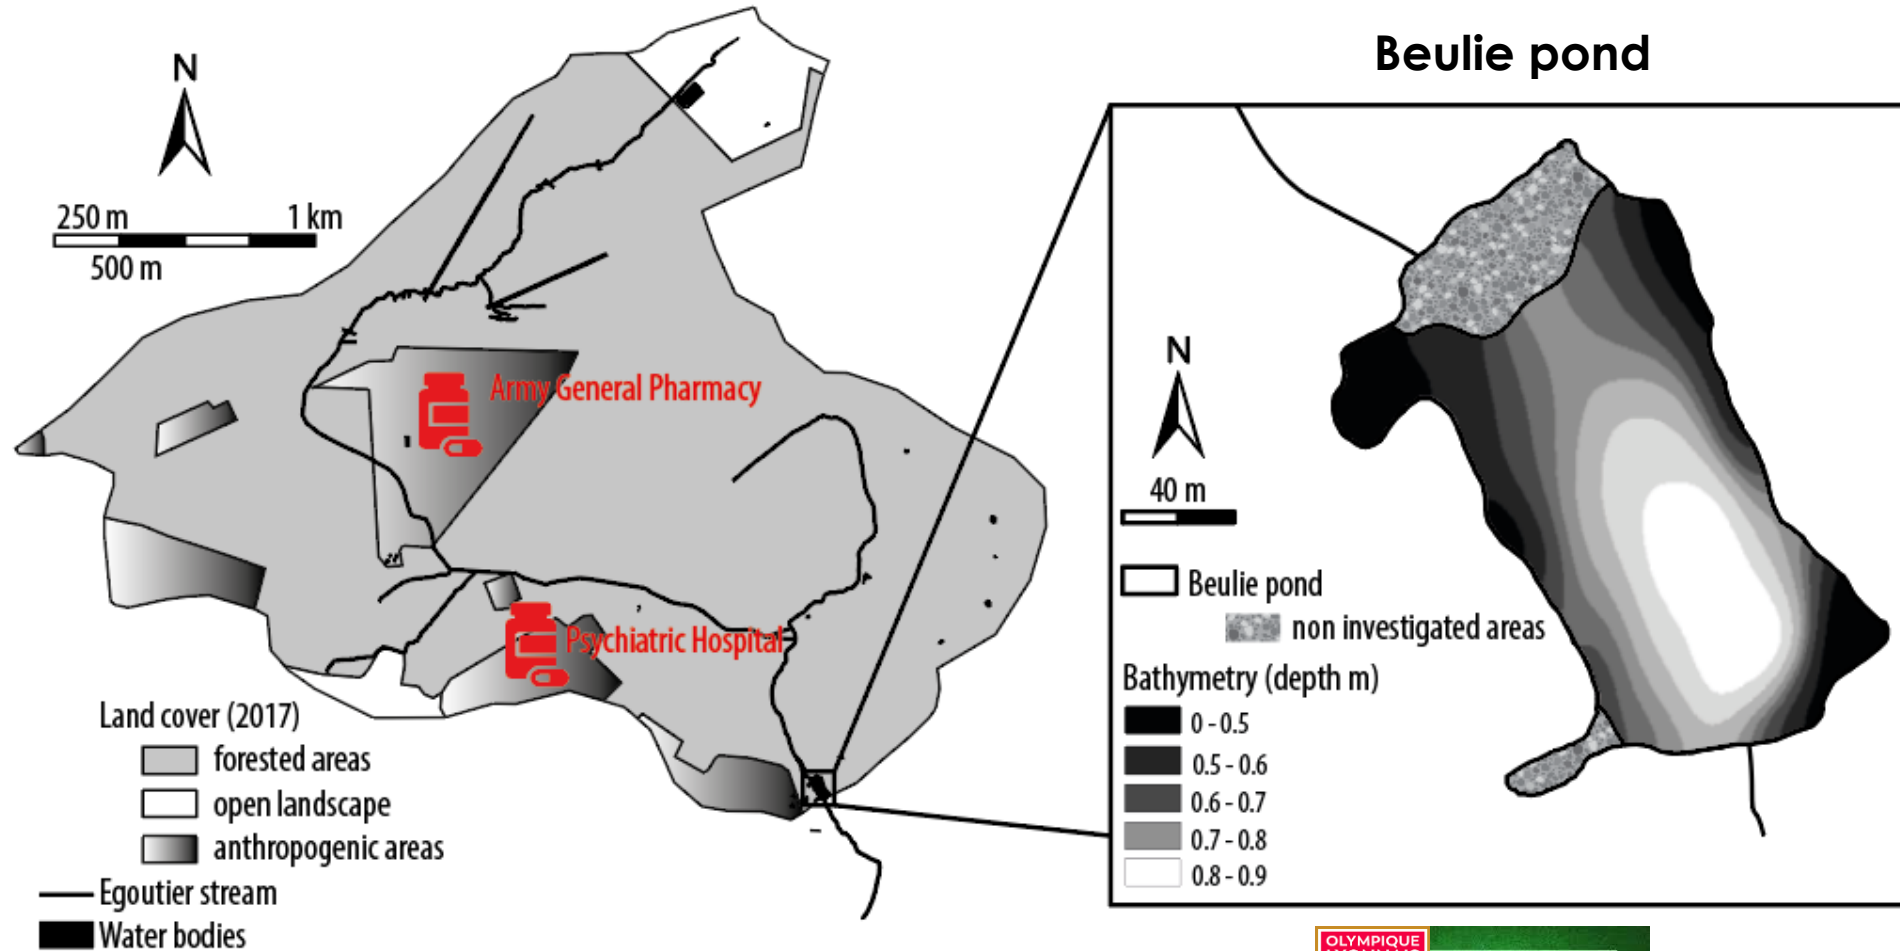

- 1 watershed subjected to anthropogenic releases
- Anthropogenic contaminants transfers' studies imply also a focus on small hydrosystems -> more sensitive/ vulnerable (Boulard et al. 2022)
- 1 retention area -> favours particulate fluxes storage (accumulation), and consequently adsorbed contaminants

- Release of inorganic and organic contaminants through wastewater treatment plants (WWTP) (red arrows) or other anthropogenic sources (blue arrows)
- Focus not only made on streams reaching outlets, but also on mass collected in retention areas, within hydrosystems

# Instrumented Egoutier Watershed (Loiret, France)

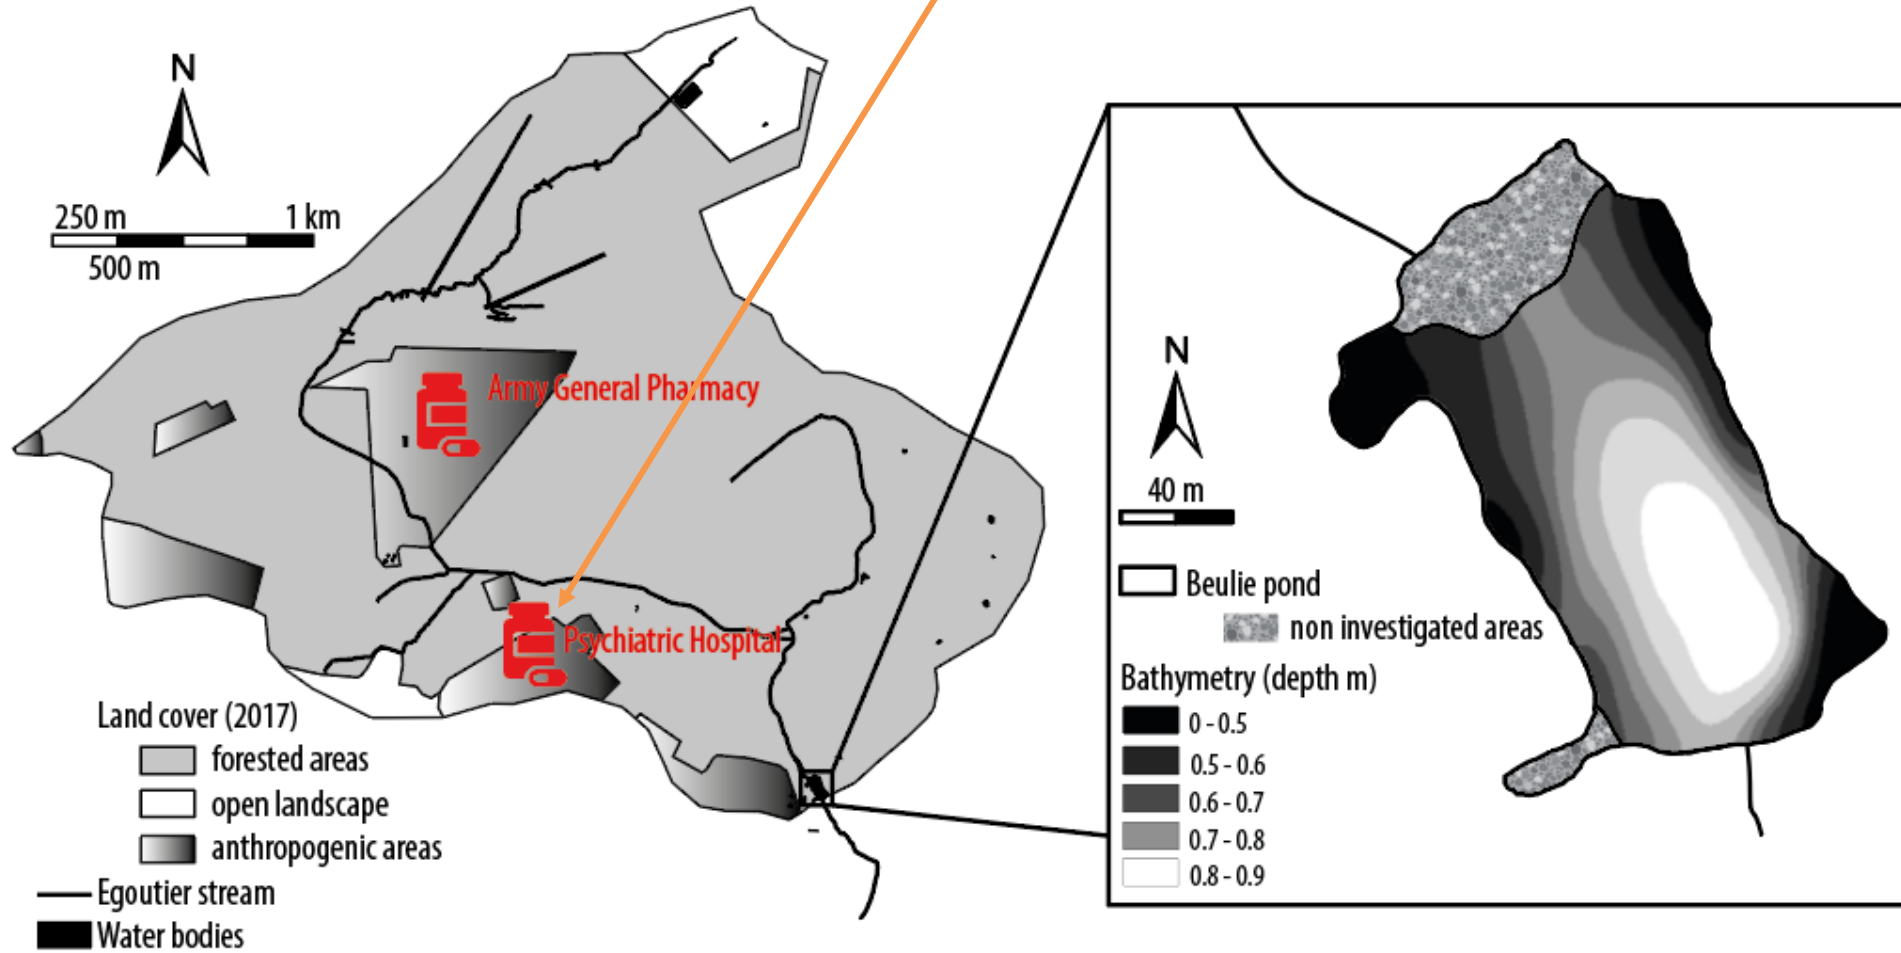

X 2

# Trace metals

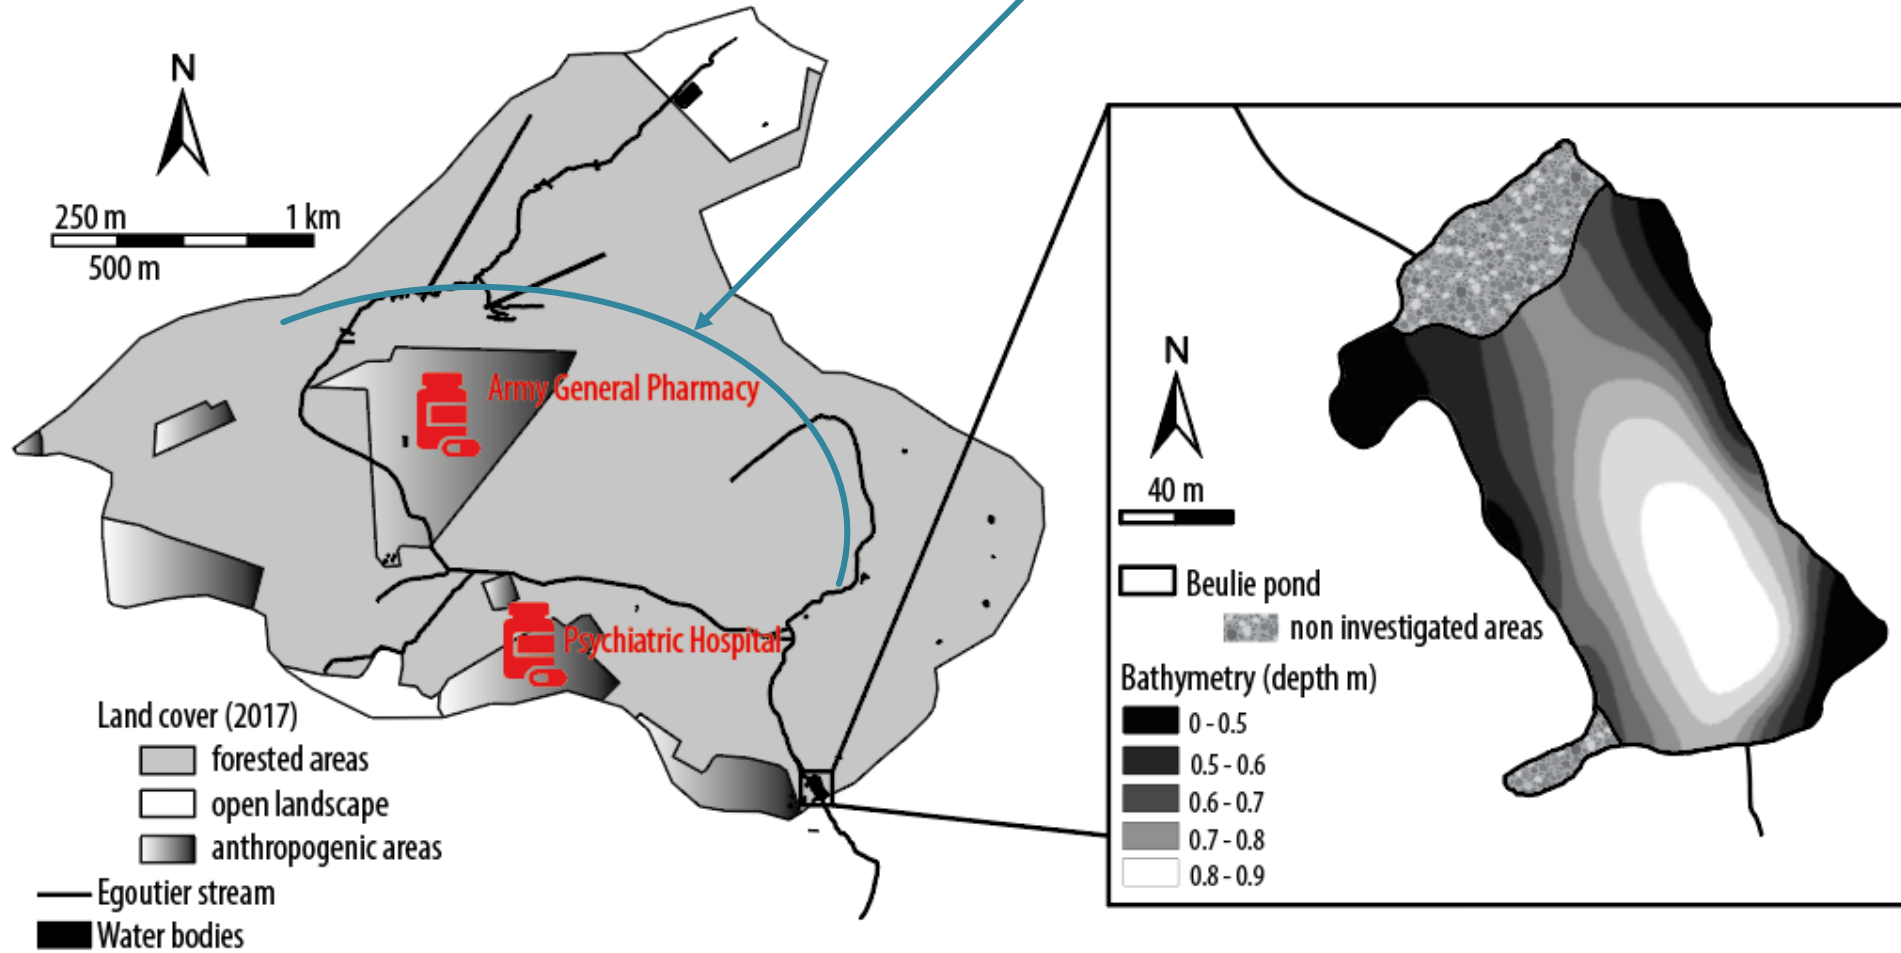

Copper (Cu): Psychiatric hospital's laundry (Ledieu 2020)

# Trace metals

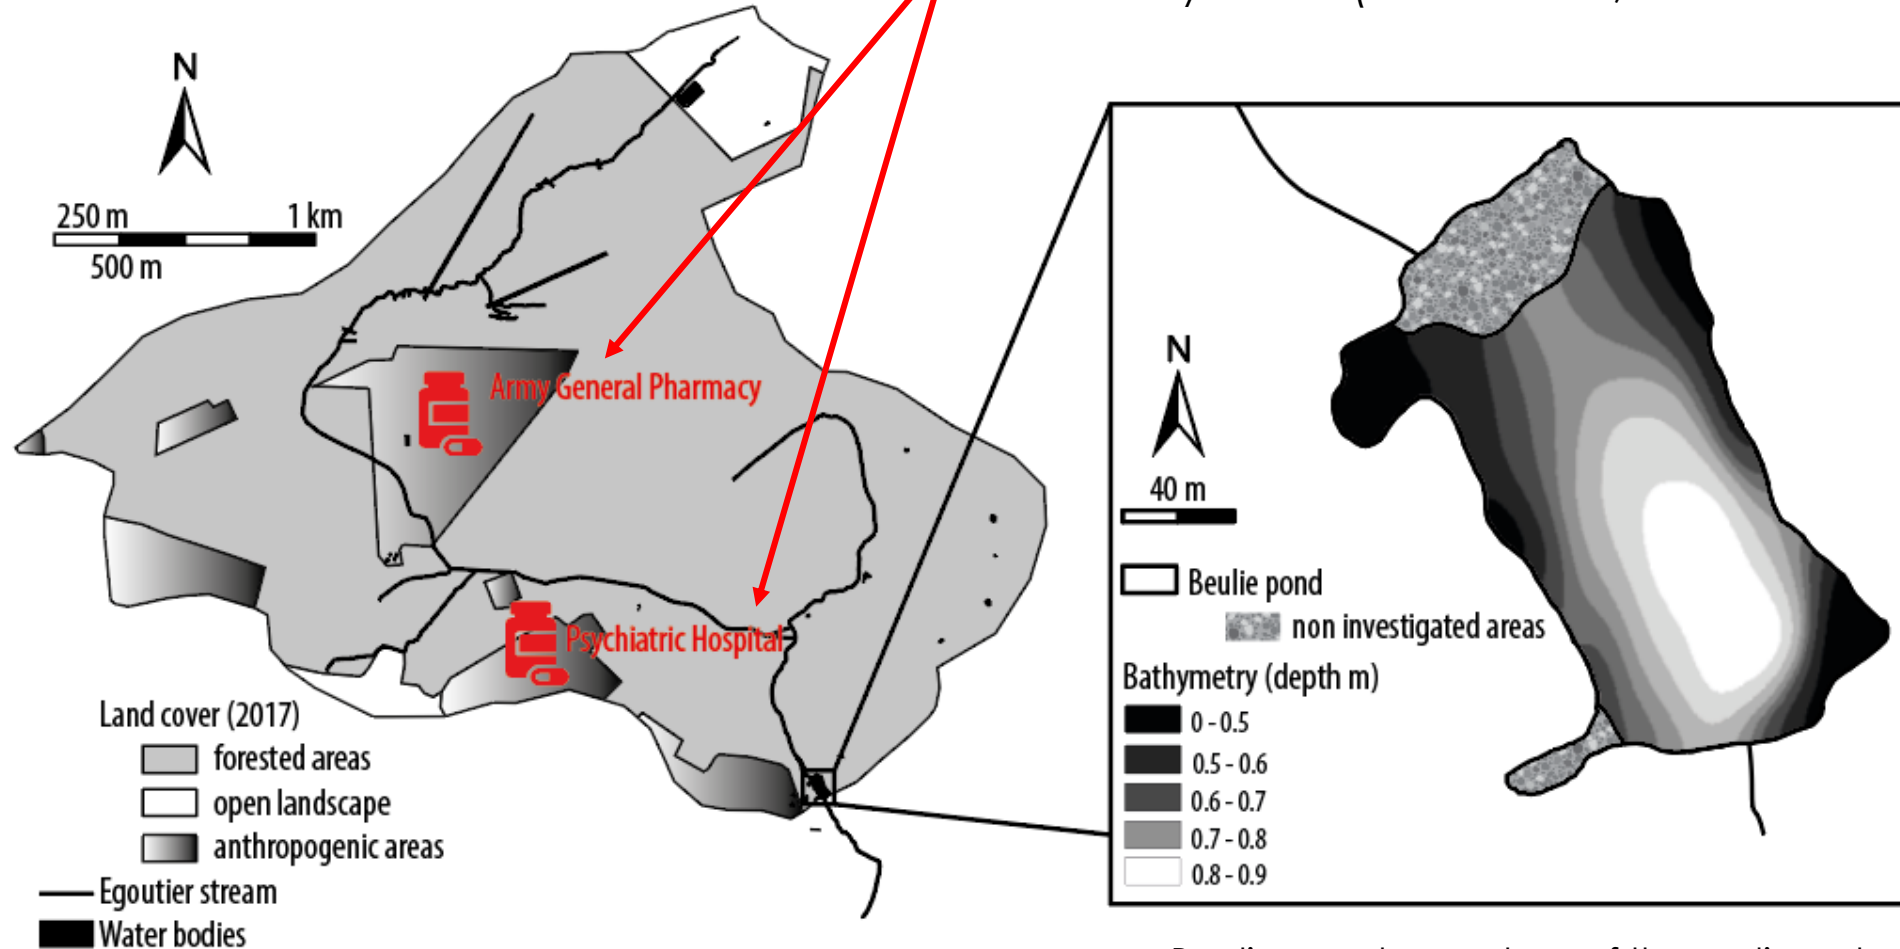

Zinc (Zn): Guardrails (Ledieu 2020)

## Organic molecules

**Pharmaceuticals:** Psychiatric hospital and Army General Pharmacy WWTP (Ledieu 2020, Ledieu et al. 2021)

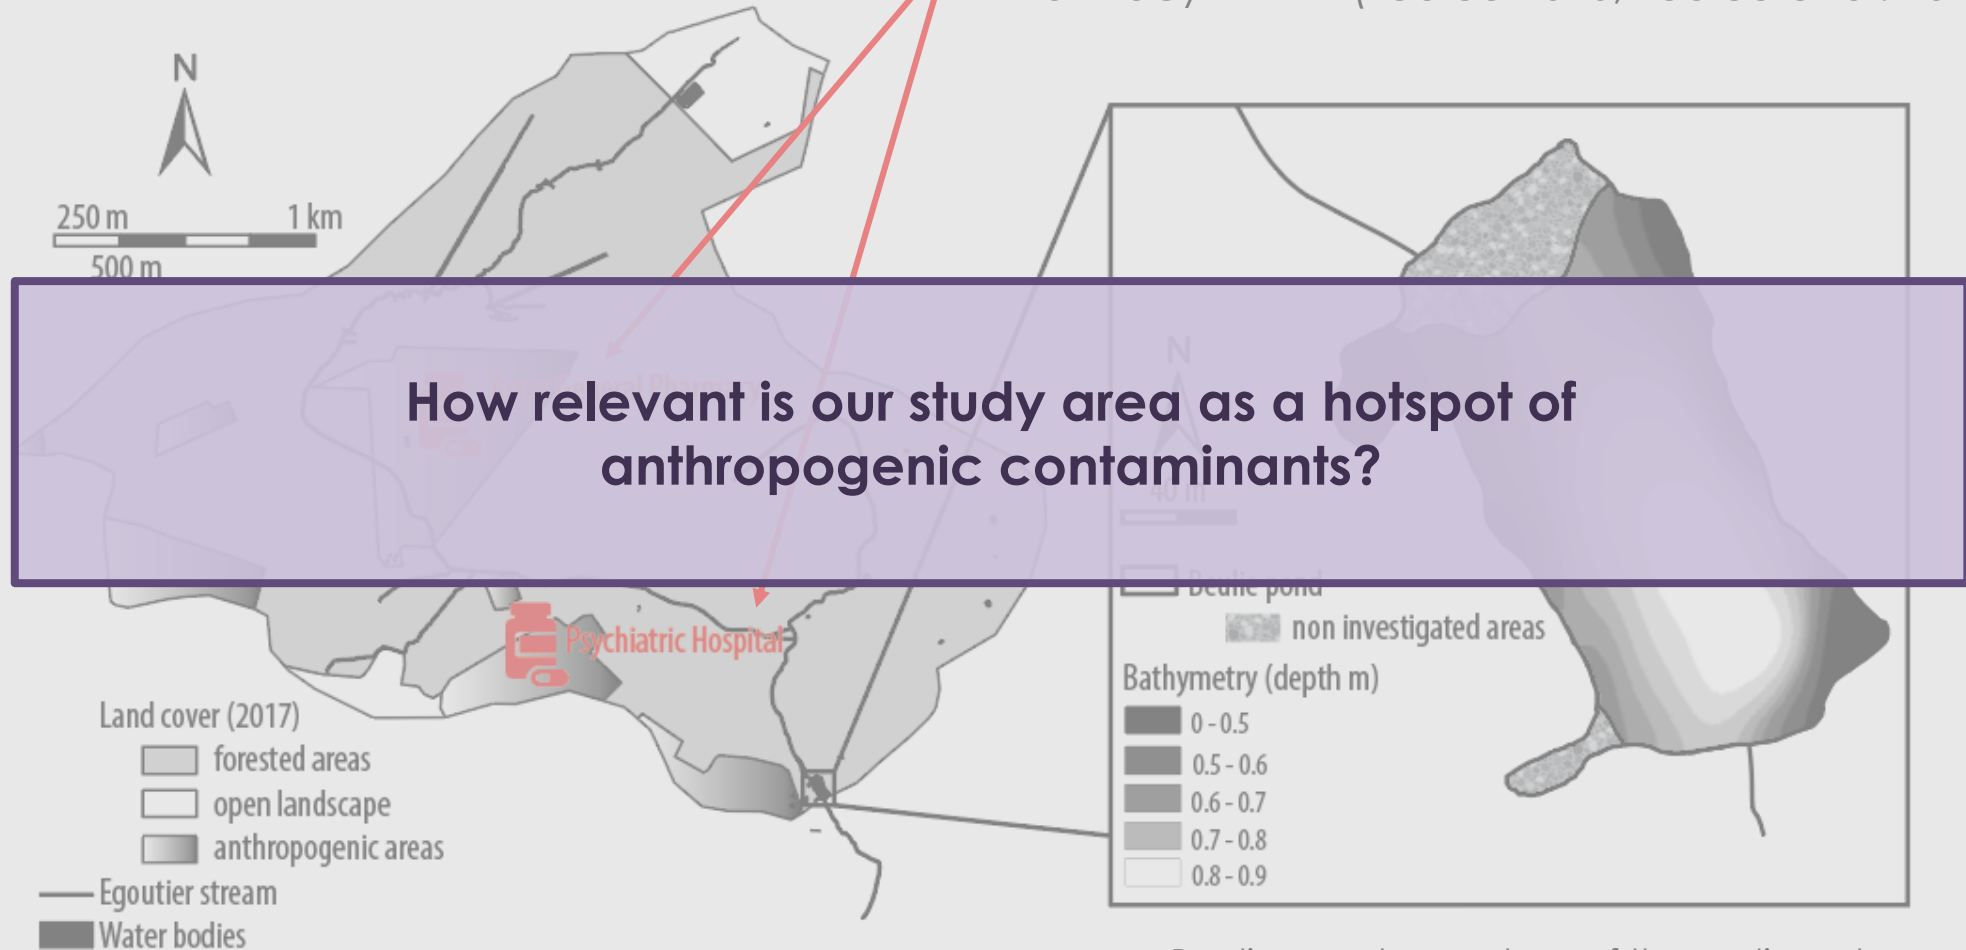

- Beulie pond -> rupture of the sedimentary cascade
- Accumulation area -> one of the contamination hotspots (Ledieu et al. 2021)

## Organic molecules

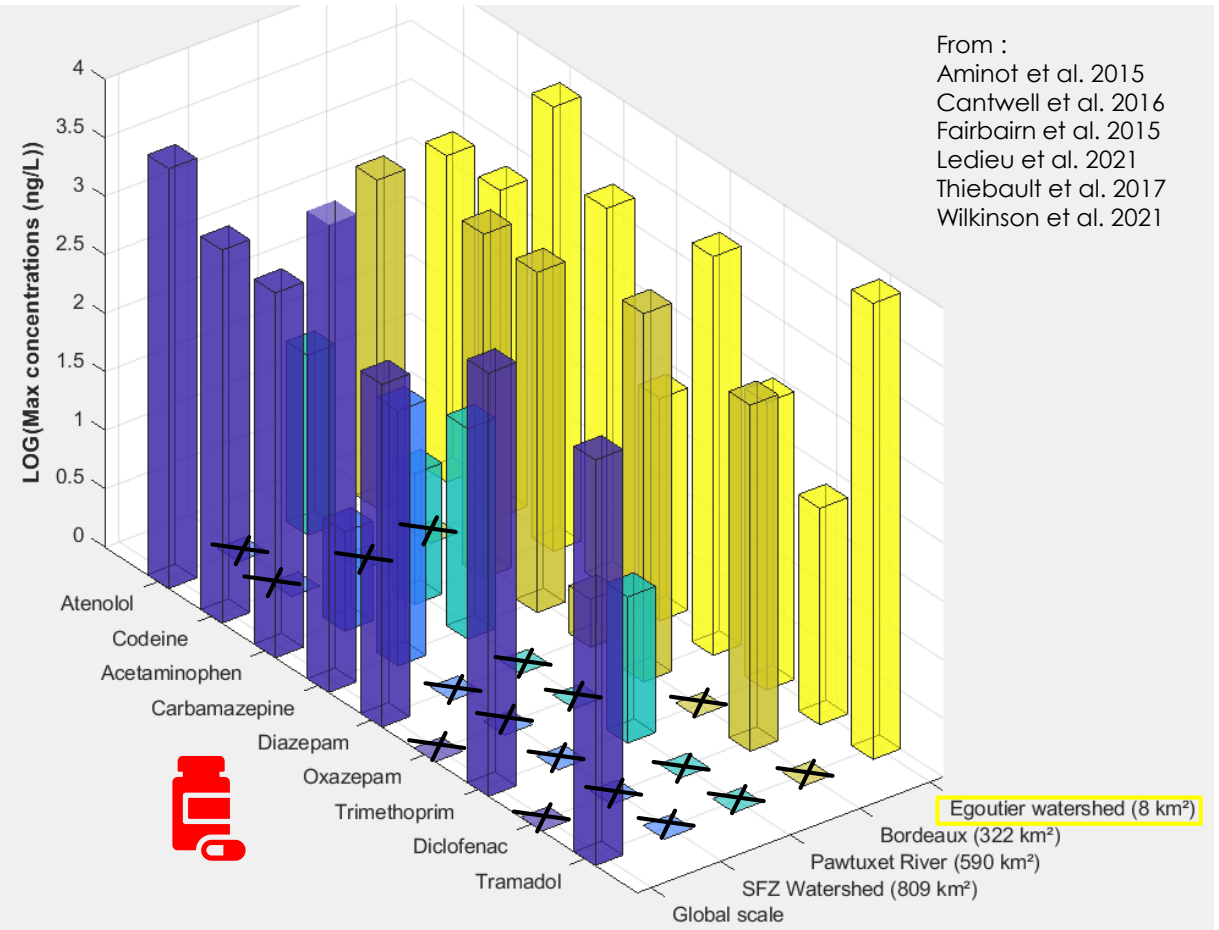

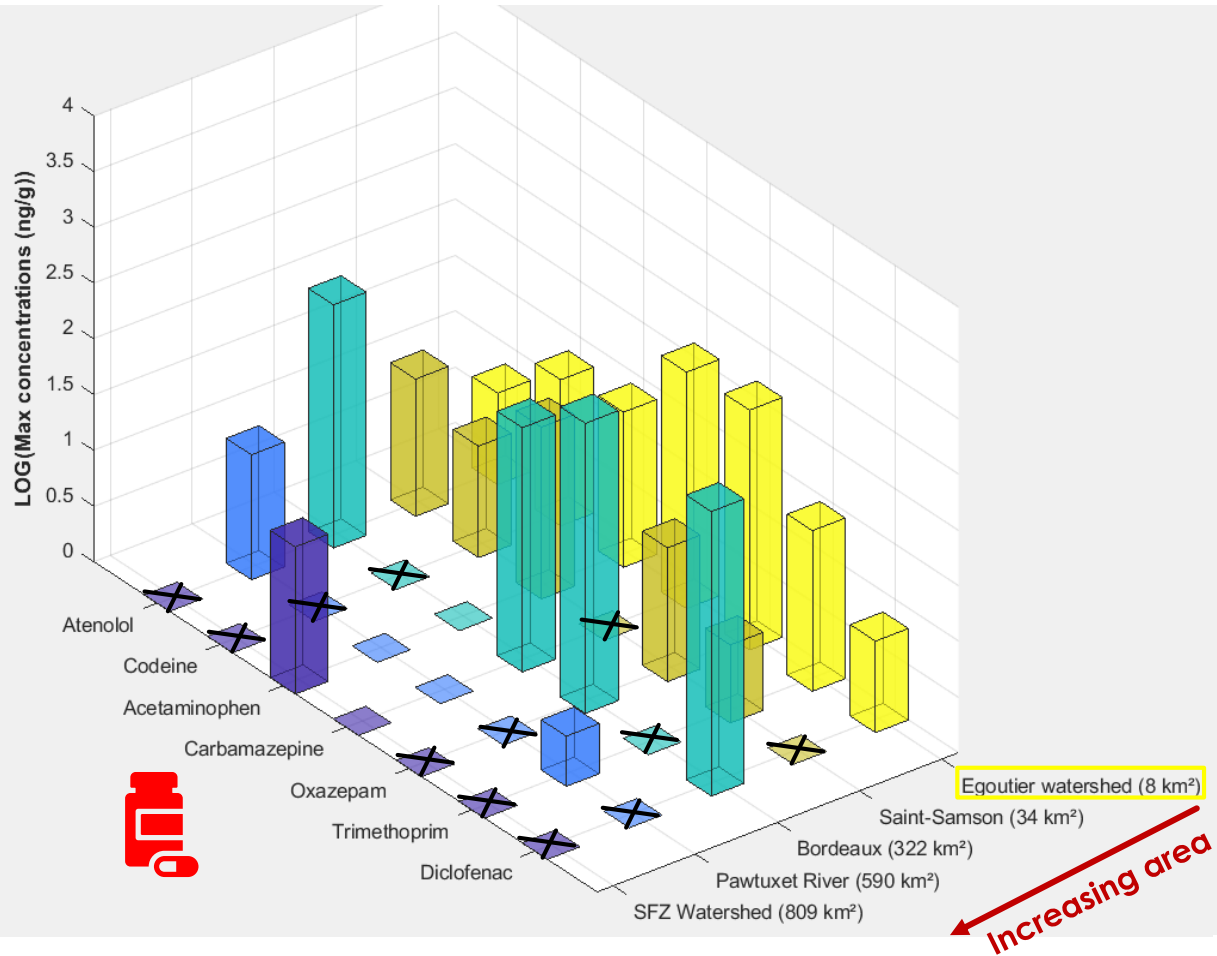

**Pharmaceuticals:** Psychiatric hospital and Army General Pharmacy WWTP (Ledieu 2020, Ledieu et al. 2021)

- Beulie pond -> rupture of the sedimentary cascade
- Accumulation area -> one of the contaminant hotspots (Ledieu et al. 2021)

PARTICULATE

AQUEOUS

From :  
Aminot et al. 2015  
Cantwell et al. 2016  
Fairbairn et al. 2015  
Ledieu et al. 2021  
Thiebault et al. 2017  
Wilkinson et al. 2021

The Egoutier watershed is subjected, as well in the aqueous as in the particulate phases, to pharmaceutical molecules contents similar to those registered in other suburban catchments

- What is the spatial distribution of the particulate phase at the pond scale ?
- How can we explain this spatial response ?
  - ❖ Pond's dynamics ?
  - ❖ Matrix effect ?
- Does the spatial distribution of the particulate phase (including potential carrying matrices) explain those of anthropogenic contaminants ?

### SAMPLING (Sediment retrieving)

- 15 interface sediment samples collected in September 2021 using an Ekman grab

### SEDIMENT SAMPLES CHARACTERIZATION

#### Granulometric and mineralogical characterizations

- Particles sizes and distribution within sediments
  - Fine particles content
  - Clays composition -> XRD
- } Laser granulometry

#### Geochemical characterizations

- Total Organic Carbon content -> Rock-Eval pyrolysis
- Trace metals characterization and quantification -> ICP-MS
- Pharmaceutical molecules characterization and quantification -> LC-MS

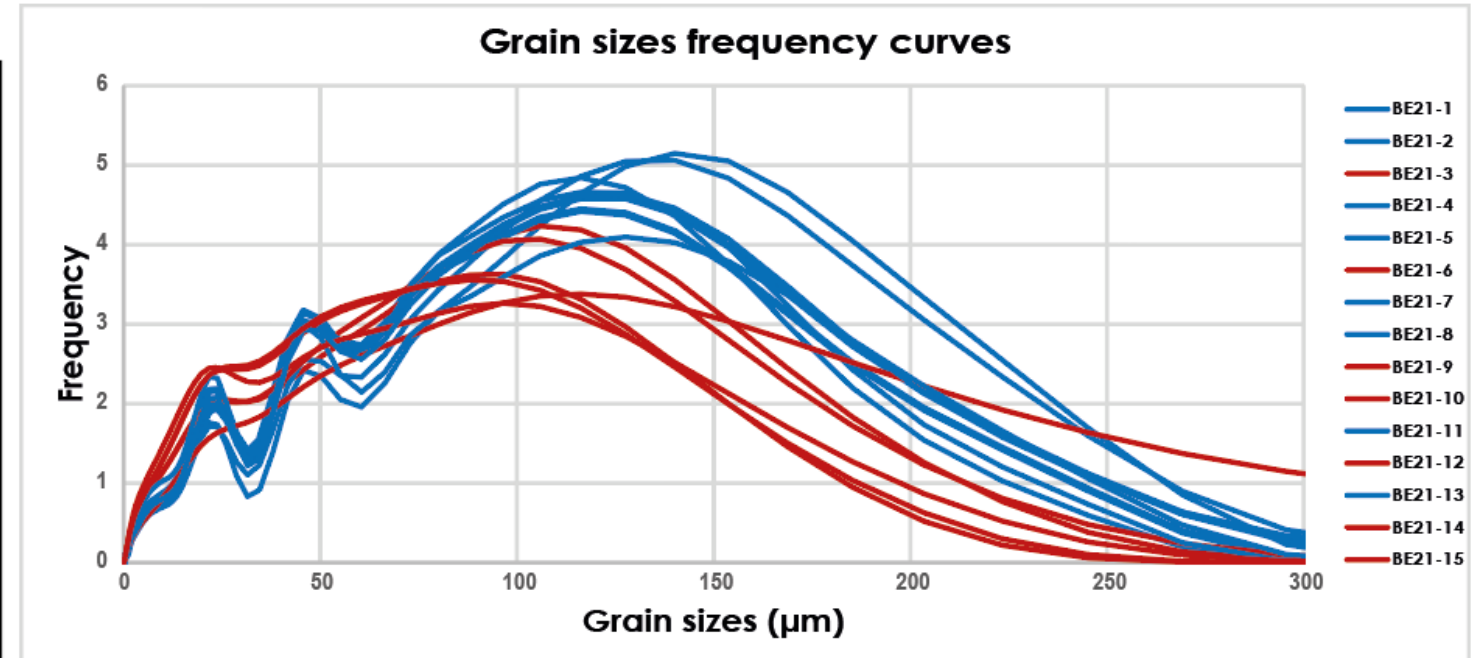

### SPATIAL DISTRIBUTION ANALYSIS

- Geographic information System

Sedimentary dynamics of interface sediment samples within the Beulie pond (Bernier-Turpin 2022)

- Unsorted granulometry
- Sorted granulometry

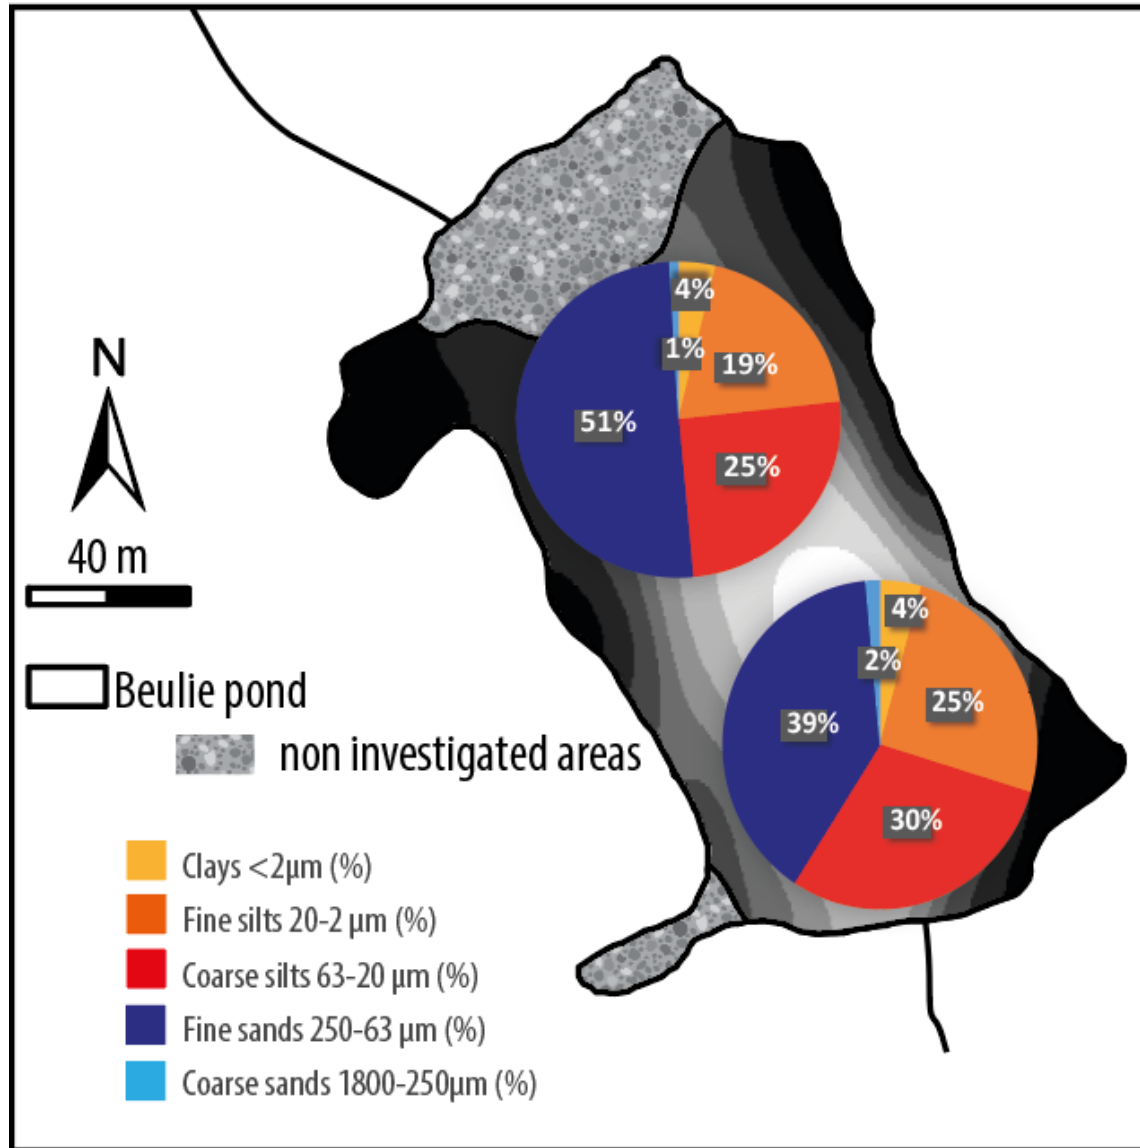

Bernier-Turpin, 2022

Grain sizes distribution :  
Upstream/Downstream cutting

- Well sorted particles are concentrated mainly in the upstream part of the pond, and in shallower areas

Granulometric distribution :  
Fine particles more represented  
downstream

- More fine particles are accumulating in the deeper areas of the pond -> granulometric sorting

Beulie Total Organic Carbon distribution (%)

Total Organic Carbon (TOC)  
distribution :  
Upstream/Downstream cutting

- TOC concentrated in shallower areas
- Potential side effect -> accumulation of organic residues such as dead leaves

Beulie Fine Particles (< 63 $\mu$ m) distribution (%)

Fine particles distribution :  
cutting in the centered-  
downstream area of the pond

- Fine particles concentrated in deeper areas
- Those areas also correspond to the «unsorted granulometry »

And now what about the spatial response of inorganic and organic contaminants ?

## Trace metals

Beulie Zinc distribution ( $\mu\text{g/g}$ )Beulie Copper distribution ( $\mu\text{g/g}$ )

- The highest contents in Cu and Zn are concentrated mainly in the upstream part of the pond
- Without evident spatial distribution
- Both might be carried by several phases, in different proportions

# Pharmaceuticals

Beulie Total Neutral Pharmaceutical molecules distribution (ng/g)

Beulie Total Cationic Pharmaceutical molecules distribution (ng/g)

- Areas with the highest contents are also the deeper
- Existing affinities between those molecules and reactive phases have to be identified

TOC = +++

= +

TOC = +++

= +

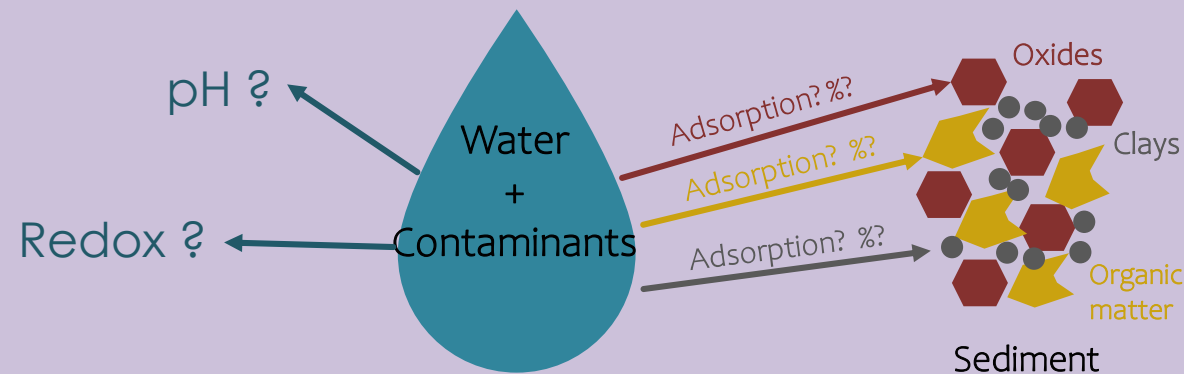

= ++

TOC = +

Fine particles = ++

= +++

- Heterogeneous spatial distribution of anthropogenic contaminants at the pond scale
  - The spatial distribution of the matrices (TOC, Fine particles) doesn't clearly explain those of anthropogenic contaminants
  - 15 samples here -> more have been collected and can be characterized as well
- Both carrying phases, molecules/trace metals, and medium properties have to be taken into account in adsorption mechanisms

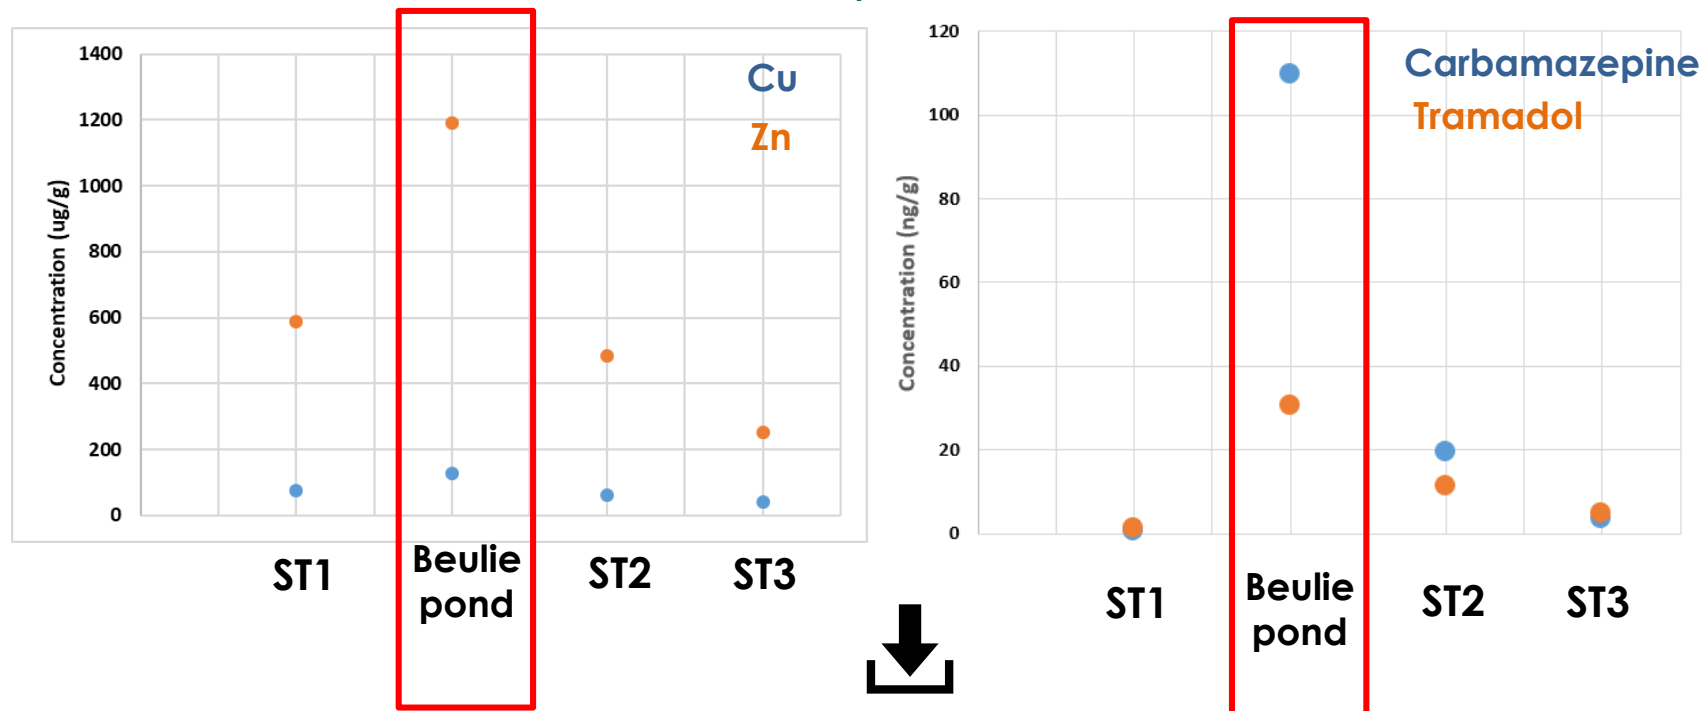

Comprehension of spatial distribution is a real concern...

Concentrations measured in the particulate phase, 2021

*Bernier-Turpin, 2022*

Beulie pond -> stock, but contaminants are crossing the pond's barrier...

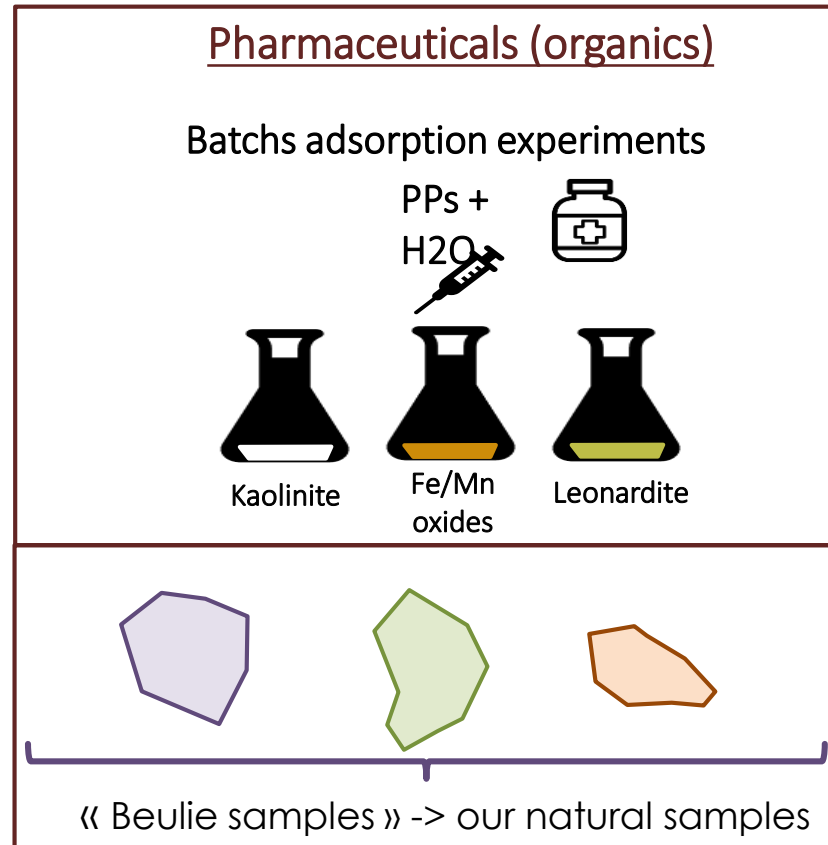

... as well as comprehension of mechanisms

## Ongoing experiments ...

- Identification and quantification of sediment's compartments
- Determination of adsorption mechanisms

Batches experiments on pure equivalent matrices

Batches using our natural samples
